

Ecma 6 Github Cheat Sheet

ECMAScript 6 Features

Arrows

Arrows are a function shorthand using the `=>` syntax. They are syntactically similar to the related feature in C#, Java 8 and CoffeeScript. They support both statement block bodies as well as expression bodies which return the value of the expression. Unlike functions, arrows share the same lexical `this` as their surrounding code.

```
// Expression bodies
var odds = evens.map(v => v + 1);
var nums = evens.map((v, i) => v + i);
var pairs = evens.map(v => ({even: v, odd: v + 1}));

// Statement bodies
nums.forEach(v => {
  if (v % 5 === 0)
    fives.push(v);
});

// Lexical this
var bob = {
  _name: "Bob",
  _friends: [],
  printFriends() {
    this._friends.forEach(f =>
      console.log(this._name + " knows " + f));
  }
}
```

More info: [MDN Arrow Functions](#)

Classes

ES6 classes are a simple sugar over the prototype-based OO pattern. Having a single convenient declarative form makes class patterns easier to use, and encourages interoperability. Classes support prototype-based inheritance, super calls, instance and static methods and constructors.

```
class SkinnedMesh extends THREE.Mesh {
  constructor(geometry, materials) {
    super(geometry, materials);

    this.idMatrix = SkinnedMesh.defaultMatrix();
    this.bones = [];
    this.boneMatrices = [];
    //...
  }
  update(camera) {
    //...
    super.update();
  }
  get boneCount() {
    return this.bones.length;
  }
  set matrixType(matrixType) {
    this.idMatrix = SkinnedMesh[matrixType]();
  }
  static defaultMatrix() {
    return new THREE.Matrix4();
  }
}
```

More info: [MDN Classes](#)

Enhanced Object Literals

Object literals are extended to support setting the prototype at construction, shorthand for `foo: foo` assignments, defining methods, making super calls, and computing property names with expressions. Together, these also bring object literals and class declarations closer together, and let object-based design benefit from some of the same conveniences.

```
var obj = {
  // __proto__
  __proto__: theProtoObj,
  // Shorthand for 'handler: handler'
  handler,
  // Methods
  toString() {
    // Super calls
    return "d " + super.toString();
  },
  // Computed (dynamic) property names
  [ 'prop_' + (() => 42)(): 42 ]: 42
};
```

More info: [MDN Grammar and types: Object literals](#)

Template Strings

Template strings provide syntactic sugar for constructing strings. This is similar to string interpolation features in Perl, Python and more. Optionally, a tag can be added to allow the string construction to be customized, avoiding injection attacks or constructing higher level data structures from string contents.

```
// Basic literal string creation
`In JavaScript '\n' is a line-feed.`

// Multiline strings
`In JavaScript this is
not legal.`

// String interpolation
var name = "Bob", time = "today";
`Hello ${name}, how are you ${time}?`

// Construct an HTTP request prefix is used to interpret the replacements and construction
POST http://foo.org/bar?a=${a}&b=${b}
Content-Type: application/json
X-Credentials: ${credentials}
{ "foo": ${foo},
  "bar": ${bar}}` (myOnReadyStateChangeHandler);
```

More info: [MDN Template Strings](#)

Destructuring

Destructuring allows binding using pattern matching, with support for matching arrays and objects. Destructuring is fail-soft, similar to standard object lookup `foo["bar"]`, producing `undefined` values when not found.

```
// list matching
var [a, , b] = [1,2,3];

// object matching
var { op: a, lhs: { op: b }, rhs: c }
  = getASTNode()

// object matching shorthand
// binds `op`, `lhs` and `rhs` in scope
var {op, lhs, rhs} = getASTNode()

// Can be used in parameter position
function g({name: x}) {
  console.log(x);
}
g({name: 5})

// Fail-soft destructuring
```

```
var [a] = [];
a === undefined;

// Fail-soft destructuring with defaults
var [a = 1] = [];
a === 1;
```

More info: [MDN Destructuring assignment](#)

Default + Rest + Spread

Callee-evaluated default parameter values. Turn an array into consecutive arguments in a function call. Bind trailing parameters to an array. Rest replaces the need for `arguments` and addresses common cases more directly.

```
function f(x, y=12) {
  // y is 12 if not passed (or passed as undefined)
  return x + y;
}
f(3) == 15
```

```
function f(x, ...y) {
  // y is an Array
  return x * y.length;
}
f(3, "hello", true) == 6
```

```
function f(x, y, z) {
  return x + y + z;
}
// Pass each elem of array as argument
f(...[1,2,3]) == 6
```

More MDN info: [Default parameters](#), [Rest parameters](#), [Spread Operator](#)

Let + Const

Block-scoped binding constructs. `let` is the new `var`. `const` is single-assignment. Static restrictions prevent use before assignment.

```
function f() {
{
  let x;
  {
    // okay, block scoped name
    const x = "sneaky";
    // error, const
    x = "foo";
  }
  // error, already declared in block
  let x = "inner";
}
}
```

More MDN info: [let statement](#), [const statement](#)

Iterators + For..Of

Iterator objects enable custom iteration like CLR `IEnumerable` or Java `Iterable`. Generalize `for..in` to custom iterator-based iteration with `for..of`. Don't require realizing an array, enabling lazy design patterns like LINQ.

```
let fibonacci = [
  [Symbol.iterator]() {
    let pre = 0, cur = 1;
    return {
      next() {
        [pre, cur] = [cur, pre + cur];
        return { done: false, value: cur }
      }
    }
  }
]
```

```

    }
}

for (var n of fibonacci) {
  // truncate the sequence at 1000
  if (n > 1000)
    break;
  console.log(n);
}

```

Iteration is based on these duck-typed interfaces (using [TypeScript](#) type syntax for exposition only):

```

interface IteratorResult {
  done: boolean;
  value: any;
}
interface Iterator {
  next(): IteratorResult;
}
interface Iterable {
  [Symbol.iterator](): Iterator
}

```

More info: [MDN for...of](#)

Generators

Generators simplify iterator-authoring using `function*` and `yield`. A function declared as `function*` returns a Generator instance. Generators are subtypes of iterators which include additional `next` and `throw`. These enable values to flow back into the generator, so `yield` is an expression form which returns a value (or throws).

Note: Can also be used to enable 'await'-like async programming, see also ES7 `await` proposal.

```

var fibonacci = {
  [Symbol.iterator]: function*() {
    var pre = 0, cur = 1;
    for (;;) {
      var temp = pre;
      pre = cur;
      cur += temp;
      yield cur;
    }
  }
}

for (var n of fibonacci) {
  // truncate the sequence at 1000
  if (n > 1000)
    break;
  console.log(n);
}

```

The generator interface is (using [TypeScript](#) type syntax for exposition only):

```

interface Generator extends Iterator {
  next(value?: any): IteratorResult;
  throw(exception: any);
}

```

More info: [MDN Iteration protocols](#)

Unicode

Non-breaking additions to support full Unicode, including new Unicode literal form in strings and new RegExp `u` mode to handle code points, as well as new APIs to process strings at the 21bit code points level. These additions support building global apps in JavaScript.

```

// same as ES5.1
"𠮷".length == 2

```

```
// new RegExp behaviour, opt-in 'u'  
"𠮷".match(/./u)[0].length == 2  
  
// new form  
"\u{20BB7}"=="𠮷"]=="\uD842\uDFB7"  
  
// new String ops  
"𠮷".codePointAt(0) == 0x20BB7  
  
// for-of iterates code points  
for(var c of "𠮷") {  
    console.log(c);  
}
```

More info: [MDN RegExp.prototype.unicode](#)

Modules

Language-level support for modules for component definition. Codifies patterns from popular JavaScript module loaders (AMD, CommonJS). Runtime behaviour defined by a host-defined default loader. Implicitly async model – no code executes until requested modules are available and processed.

```
// lib/math.js  
export function sum(x, y) {  
    return x + y;  
}  
export var pi = 3.141593;  
  
// app.js  
import * as math from "lib/math";  
alert("2π = " + math.sum(math.pi, math.pi));  
  
// otherApp.js  
import {sum, pi} from "lib/math";  
alert("2π = " + sum(pi, pi));
```

Some additional features include `export default` and `export *`:

```
// lib/mathplusplus.js  
export * from "lib/math";  
export var e = 2.71828182846;  
export default function(x) {  
    return Math.log(x);  
}  
  
// app.js  
import ln, {pi, e} from "lib/mathplusplus";  
alert("2π = " + ln(e)*pi*2);
```

More MDN info: [import statement](#), [export statement](#)

Module Loaders

Module loaders support:

- Dynamic loading
- State isolation
- Global namespace isolation
- Compilation hooks
- Nested virtualization

The default module loader can be configured, and new loaders can be constructed to evaluate and load code in isolated or constrained contexts.

```
// Dynamic loading – 'System' is default loader
```

```

System.import('lib/math').then(function(m) {
  alert("2π = " + m.sum(m.pi, m.pi));
});

// Create execution sandboxes – new Loaders
var loader = new Loader({
  global: fixup(window) // replace 'console.log'
});
loader.eval("console.log('hello world!');");
 
// Directly manipulate module cache
System.get('jquery');
System.set('jquery', Module({$: $})); // WARNING: not yet finalized

```

Map + Set + WeakMap + WeakSet

Efficient data structures for common algorithms. WeakMaps provides leak-free object-key'd side tables.

```

// Sets
var s = new Set();
s.add("hello").add("goodbye").add("hello");
s.size === 2;
s.has("hello") === true;

// Maps
var m = new Map();
m.set("hello", 42);
m.set(s, 34);
m.get(s) === 34;

// Weak Maps
var wm = new WeakMap();
wm.set(s, { extra: 42 });
wm.size === undefined

// Weak Sets
var ws = new WeakSet();
ws.add({ data: 42 });
// Because the added object has no other references, it will not be held in the set

```

More MDN info: [Map](#), [Set](#), [WeakMap](#), [WeakSet](#)

Proxies

Proxies enable creation of objects with the full range of behaviors available to host objects. Can be used for interception, object virtualization, logging/profiling, etc.

```

// Proxying a normal object
var target = {};
var handler = {
  get: function (receiver, name) {
    return `Hello, ${name}!`;
  }
};

var p = new Proxy(target, handler);
p.world === 'Hello, world!';

```

```

// Proxying a function object
var target = function () { return 'I am the target'; };
var handler = {
  apply: function (receiver, ...args) {
    return 'I am the proxy';
  }
};

var p = new Proxy(target, handler);
p() === 'I am the proxy';

```

There are traps available for all of the runtime-level meta-operations:

```

var handler =
{
  get:....,
  set:....,
  has:....,
  deleteProperty:....,
  apply:....,
  construct:....,
  getOwnPropertyDescriptor:....,
  defineProperty:....,
  getPrototypeOf:....,
  setPrototypeOf:....,
  enumerate:....,
  ownKeys:....,
  preventExtensions:....,
  isExtensible:...
}

```

More info: [MDN Proxy](#)

Symbols

Symbols enable access control for object state. Symbols allow properties to be keyed by either `string` (as in ES5) or `symbol`. Symbols are a new primitive type. Optional `description` parameter used in debugging - but is not part of identity. Symbols are unique (like gensym), but not private since they are exposed via reflection features like `Object.getOwnPropertySymbols`.

```

var MyClass = (function() {

  // module scoped symbol
  var key = Symbol("key");

  function MyClass(privateData) {
    this[key] = privateData;
  }

  MyClass.prototype = {
    doStuff: function() {
      ... this[key] ...
    }
  };

  return MyClass;
})();

var c = new MyClass("hello")
c["key"] === undefined

```

More info: [MDN Symbol](#)

Subclassable Built-ins

In ES6, built-ins like `Array`, `Date` and DOM `Element`s can be subclassed.

Object construction for a function named `Ctor` now uses two-phases (both virtually dispatched):

- Call `Ctor[@@create]` to allocate the object, installing any special behavior
- Invoke constructor on new instance to initialize

The known `@@create` symbol is available via `Symbol.create`. Built-ins now expose their `@@create` explicitly.

```

// Pseudo-code of Array
class Array {
  constructor(...args) { /* ... */ }
  static [Symbol.create]() {
    // Install special [[DefineOwnProperty]]
    // to magically update 'length'
  }
}

// User code of Array subclass
class MyArray extends Array {
  constructor(...args) { super(...args); }
}

```

```

}

// Two-phase 'new':
// 1) Call @@create to allocate object
// 2) Invoke constructor on new instance
var arr = new MyArray();
arr[1] = 12;
arr.length == 2

```

Math + Number + String + Array + Object APIs

Many new library additions, including core Math libraries, Array conversion helpers, String helpers, and Object.assign for copying.

```

Number.EPSILON
Number.isInteger(Infinity) // false
Number.isNaN("NaN") // false

Math.acosh(3) // 1.762747174039086
Math.hypot(3, 4) // 5
Math.imul(Math.pow(2, 32) - 1, Math.pow(2, 32) - 2) // 2

"abcde".includes("cd") // true
"abc".repeat(3) // "abcabcabc"

Array.from(document.querySelectorAll('*')) // Returns a real Array
Array.of(1, 2, 3) // Similar to new Array(...), but without special one-arg behavior
[0, 0, 0].fill(7, 1) // [0,7,7]
[1, 2, 3].find(x => x == 3) // 3
[1, 2, 3].findIndex(x => x == 2) // 1
[1, 2, 3, 4, 5].copyWithin(3, 0) // [1, 2, 3, 1, 2]
["a", "b", "c"].entries() // iterator [0, "a"], [1,"b"], [2,"c"]
["a", "b", "c"].keys() // iterator 0, 1, 2
["a", "b", "c"].values() // iterator "a", "b", "c"

Object.assign(Point, { origin: new Point(0,0) })

```

More MDN info: [Number](#), [Math](#), [Array.from](#), [Array.of](#), [Array.prototype.copyWithin](#), [Object.assign](#)

Binary and Octal Literals

Two new numeric literal forms are added for binary (`b`) and octal (`o`).

```

0b111110111 === 503 // true
0o767 === 503 // true

```

Promises

Promises are a library for asynchronous programming. Promises are a first class representation of a value that may be made available in the future. Promises are used in many existing JavaScript libraries.

```

function timeout(duration = 0) {
    return new Promise((resolve, reject) => {
        setTimeout(resolve, duration);
    })
}

var p = timeout(1000).then(() => {
    return timeout(2000);
}).then(() => {
    throw new Error("hmm");
}).catch(err => {
    return Promise.all([timeout(100), timeout(200)]);
})

```

More info: [MDN Promise](#)

Reflect API

Full reflection API exposing the runtime-level meta-operations on objects. This is effectively the inverse of the Proxy API, and allows writing code according to the same meta-conventions as the language's standard reflection API.

API, and allows making calls corresponding to the same meta-operations as the proxy traps. Especially useful for implementing proxies.

```
// No sample yet
```

More info: [MDN Reflect](#)

Tail Calls

Calls in tail-position are guaranteed to not grow the stack unboundedly. Makes recursive algorithms safe in the face of unbounded inputs.

```
function factorial(n, acc = 1) {
  'use strict';
  if (n <= 1) return acc;
  return factorial(n - 1, n * acc);
}

// Stack overflow in most implementations today,
// but safe on arbitrary inputs in ES6
factorial(100000)
```
